

Multi-Arm Trials

A Practical Introduction to Simulating Complex Trial Designs

Multiple treatments

We have K experimental treatments $T_1, \dots, T_K$ and control available.

Suppose that response to T_k are

$$Y_{ki} \sim \mathcal{N}(\mu_k, \sigma^2)$$

Interest is in testing K distinct null hypotheses

$$H_{0k} : \mu_0 \geq \mu_k$$

$$H_{1k} : \mu_0 < \mu_k$$

for $k = 1, \dots, K$ and where T_0 is the control treatment.

A simple multi-arm study

In a multi-arm study we only recruit from patients to the control treatment once, using a common control for the trial

Estimation

For each arm $k = 0, \dots, K$ we find estimates $\bar{y}_k$ and corresponding Z-values for $k = 1, \dots, K$

$$Z_k = \frac{1}{\sigma} \sqrt{\frac{n_0 n_k}{n_0 + n_k}} (\bar{y}_k - \bar{y}_0)$$

where n_k is the number of patients treated on T_k and

$$\mathbf{Z} \sim N(\mathbf{d}, \mathbf{V})$$

with

$$d_k = \frac{1}{\sigma} \sqrt{\frac{n_0 n_k}{n_0 + n_k}} (\mu_k - \mu_0); \quad v_{kk'} = \sqrt{\frac{n_k n_{k'}}{(n_0 + n_k)(n_0 + n_{k'})}}, \quad k \neq k'; \quad v_{kk} = 1$$

Selecting the best treatment

Select treatment T_{k^*} where

$$Z_{k^*} = \max(Z_1, \dots, Z_K)$$

provided that the null hypothesis H_{0k} is rejected

$$Z_{k^*} \geq c$$

Otherwise, make no selection

Specifying the accuracy

Under the global null:

$$\nu = P(\text{select a treatment} \mid \mu_0 = \mu_1 = \cdots = \mu_K)$$

Under the alternative:

$$\begin{aligned} 1 - \eta &= P(\text{select } T_1 \mid \mu_1 = \mu_0 + \delta \text{ and} \\ &\quad \mu_{k'} = \mu_0 + \delta_0, \ k' = 2, \dots, K) \end{aligned}$$

with $0 \leq \delta_0 < \delta$.

- ▶ δ is the interesting treatment effect
- ▶ δ_0 is the uninteresting treatment effect
- ▶ This is typically referred to as a *Least Favourable Configuration*

Set ν to be small and $1 - \eta$ to be large

Familywise Error Rate (FWER)

Given multiple hypotheses the simply controlling the type I error rate is not sufficient, we require strong control of the FWER

Let $\boldsymbol{\mu} = (\mu_0, \mu_1, \dots, \mu_K)$ then strong control is achieved when

$$\mathbb{P}(\text{Reject any combination of true null hypotheses}) \leq \nu \text{ for all } \boldsymbol{\mu}.$$

The Dunnett approach

Suppose we are testing H_{0,k^*} , let

$$Z_{k^*} = \operatorname{argmax}_{k \in 1, \dots, K} Z_k$$

choosing c such that when $\mu_k \geq \mu_0$, we have

$$\mathbb{P}(Z_{k^*} > c) \leq \nu$$

we reject H_{0,k^*} when $Z_{k^*} > c$.

Syntax in R

R code

```
> #find the critical region for a test  
> alpha<-0.05  
> qnorm(1-alpha)  
[1] 1.644854
```

R code

```
> #find the critical region for correlated tests  
> require(mvtnorm)  
> corr<-matrix(c(1,0.5,0.5,1),ncol=2)  
> corr  
      [,1] [,2]  
[1,]  1.0  0.5  
[2,]  0.5  1.0  
> qmvnorm((1-alpha),tail="lower.tail",  
mean=c(0,0),corr=corr)$quantile  
[1] 1.916399
```

Where simulation can help

- ▶ Assessment of power for individual hypotheses;
- ▶ Behaviour under different configurations (for the given sample size);
- ▶ Operating characteristics under non-normal endpoints;
- ▶ Accuracy of assumption of equal variances;
- ▶ ...

Your best friends for the rest of the day....

Simulating (random) outcomes:

R code

```
> rnorm(n=5,mean=0,sd=1)
[1] 0.8535184 0.1053162 2.4155607 1.9475439 0.4064240
```

```
> rmvnorm(n=3,mean=c(0,0),sigma=corr)
      [,1]      [,2]
[1,] 1.0394488 0.5164349
[2,] 0.3408723 0.8562483
[3,] 0.5389829 -0.1303348
```

“For” loops

R code

```
for (i in 1:nsims){
  ...}
```
